ABSTRACT

In this paper investigates bending behavior of P-FGM beam resting on the elastic foundation including Winkler springs. Exact solutions obtained from closed-form formulation based on generalized shear deformation beam theory which can be adapted to various beams theories for bending analysis of such beam are presented. An accuracy of the present solutions is validated numerically by comparisons with some available results in the literature. Various significant parameters P-FGM volume fraction, spring constant factors, beam thickness, etc. are taken into investigation. According to the numerical results, it is revealed that the deflection of the beams is found to decrease as the increase of spring constant factors.

Keywords: P-FGM Beams, Winkler Elastic Foundation, Neutral Surface, Bending, Higher-order Theory.

1. INTRODUCTION

Functionally graded material (FGM) is a new class of composite material whose compositions vary according to the required performance. It is produced by a continuously graded variation of the volume fractions of the constituents (Koizumi 1997) [1], the FGM is thus suitable for various applications, such as thermal coatings of barrier for ceramic engines, gas turbines, nuclear fusions, optical thin layers, biomaterial electronics, etc.

Due to increasing of FGM applications in engineering structures, many beam theories have been developed to predict the response of functionally graded (FG) beams (Huu-Tai Thai 2012) [2]. The classical beam theory (CBT) known as Euler–Bernoulli beam theory is the simplest one and is applicable to slender FG beams only. For moderately deep FG beams, the CBT underestimates deflection and overestimates natural frequency due to ignoring the transverse shear deformation effect (Yang J, 2008) [3] (Alshorbagy 2011) [4]. The first-order shear deformation beam theory (FTB) known as Timoshenko beam theory has been proposed to overcome the limitations of the CBT by accounting for the transverse shear deformation effect. Since the FBT violates the zero shear stress conditions on the top and bottom surfaces of the beam, a shear correction factor is required to account for the discrepancy between the actual stress state and the assumed constant stress state(Chakraborty A, 2003) [5] (Wei D, 2012) [6] To avoid the use of a shear correction factor and have a better prediction of response of FG beams, higher-order shear deformation theories have been proposed, notable among them are the third-order theory of Reddy Reddy JN. 1984 [8–12], the sinusoidal theory of Touratier [13], the hyperbolic theory of Soldatos [14], the exponential theory of Karama et al. [15], and the unified formulation of Carrera [16,17]. Higher order shear deformation theories can be developed based on the assumption of a higher-order variation of axial displacement through the depth of the beam [18–19] or both axial and transverse displacements through the depth of the beam (i.e., via the use of a unified formulation) [20–21].

In this paper, a new model of higher-order shear deformation beam theories for bending of FG beams are developed based on the neutral axe (BOUKHARI 2016) [7], [23] and higher-order variation of axial displacement through the depth of the beam resting on elastic foundation (type winkler). The proposed theories satisfy the zero traction boundary conditions on the top and bottom surfaces of the beam, thus a shear correction factor is not required. In addition, these theories have strong similarities with the CBT in many aspects such as equations of motion, boundary conditions, and stress resultant expressions. Material properties of FG beams are assumed to vary according to a power law distribution of the volume fraction of the constituents. Equations of motion and boundary conditions are derived from Hamilton's principle. Analytical solutions for bending are obtained for a simply supported beam. Numerical examples are presented to show the validity and accuracy of present shear deformation theories. The effects of power law index and spring factors on the bending responses of FG beams are investigated.
2. MODEL ANALYTIC

The model used is a beam FG with length L and rectangular cross section b x h, with b being the width and h being the height. The x, y, and z coordinates are taken along the length, width, and height of the beam, respectively.

The x axis is considered indeformable of the beam axis. The x axis coincides with the median axis of the beam and the z axis is perpendicular to the xy plane. The y axis is considered deformable of the beam axis. But if the origin of the coordinate system is properly selected so that it is positioned on the neutral axis, the material properties of the FG beam will be symmetrical about this reference. To specify the position of the neutral axis of the FG beam; different references are considered to measure z to know and measured from the centerline and the neutral axis of the beam is shown in figure 2.

![Figure 1. Geometry and coordinate system for a rectangular FG beam resting on winkler elastic foundations.](image)

![Figure 2. The position of midlle surface and neutral surface for a functionnall graded beams (BOUKHARI A.2016) [7],[23].](image)

The material properties of the FG beam based on the coordinate of the thickness.

\[
P(z) = P_m + \left(P_c - P_m \right) \left( \frac{z_{ms} + C}{h} + \frac{1}{2} \right) \rho
\]

The position of the neutral axis of the beam FG is determined from (Bouremana et al, 2013 [10]; Ould Larbi et al, 2013 [11]). Therefore, the position of the neutral axis can be obtained by.

\[
P(z) = P_m + \left(P_c - P_m \right) \left( \frac{z_{ms} + C}{h} + \frac{1}{2} \right) \rho
\]

The displacement fields of the present model of higher-order shear deformation beam theories are given in a general form as.

\[
u(x, z_{ms}) = u_0(x) - (z_{ms} + c) \frac{\partial w_b}{\partial x} - f(z_{ms}) \frac{\partial w_s}{\partial x} \quad (3)
\]

\[
w(x, z_{ms}) = w_b(x) + w_s(x)
\]

where \( u \) is the axial displacement of a point on the midplane of the beam; \( w_b \) and \( w_s \) are the bending and shear components of transverse displacement of a point on the midplane of the beam; and \( f(z) \) is a shape function determining the distribution of the transverse shear strain and shear stress through the depth of the beam. The shape functions \( f(z) \) are chosen to satisfy the stress-free boundary conditions on the top and bottom surfaces of the beam.

\[
f(z_{ms}) = \frac{\pi}{\sinh\left( \frac{\pi}{h} \left( z_{ms} + c \right) \right)} - \left( z_{ms} + c \right)
\]

The linear constitutive relationships of the FG beams can be written as

\[
\sigma_x = Q_{11} \varepsilon_x, \quad \tau_{xz} = Q_{55} \gamma_{xz}
\]

\[
Q_{11} = E(z_{ms}) C, \quad Q_{55} = \frac{E(z_{ms})}{2(1 + \nu)}
\]

3. EQUATION OF MOTION

The equilibrium equations are obtained using the principle of virtual displacements is applied to derive the equations of equilibrium and natural boundary conditions of a beam.

\[
\delta U + \delta V - f_\varepsilon = 0 \quad (9)
\]

\[
\delta U \quad \text{is the virtual variation of strain energy;}
\]

\[
\delta V \quad \text{is the virtual variation of the work of external forces;}
\]

\[
f_\varepsilon \quad \text{is the density of reaction force of the foundation.}
\]

\[
\delta U = \int \left( \sigma_{xx} \delta \varepsilon_x + \tau_{xz} \delta \gamma_{xz} \right) dv
\]
\[
\delta V = - \int_A q \delta w dA \\
\delta f_e = K_w w
\]

La solution de Navier est utilisée pour déterminer les solutions analytiques pour les poutres simplement appuyées. La solution est supposée comme suit.

\[
u(x) = \sum_{n=1}^\infty U_n \cos(\alpha x)
\]

\[
w_s(x) = \sum_{n=1}^\infty W_{bn} \sin(\alpha x)
\]

\[
w_r(x) = \sum_{n=1}^\infty W_{rn} \sin(\alpha x)
\]

\[
\alpha = n\pi / L; \left( U_n, W_{bn}, W_{rn} \right)
\]

Les amplitudes sont représentées par les transverse load q is also developed in Fourier series as follows.

\[
q(x) = \sum_{n=1}^\infty Q_n \sin(\alpha x);
\]

\[
Q_n = \frac{4q_0}{n\pi} \quad (n=1,3,5,...)
\]

Analytical solutions can be obtained in the following condensed form.

\[
\begin{bmatrix}
    s_{11} & s_{12} & s_{13} \\
    s_{21} & s_{22} & s_{23} \\
    s_{31} & s_{32} & s_{33}
\end{bmatrix}
\begin{bmatrix}
    U_n \\
    W_{bn} \\
    W_{rn}
\end{bmatrix}
= \begin{bmatrix}
    0 \\
    Q_n \\
    Q_n
\end{bmatrix}
\]

\[
\begin{align}
& s_{11} = A\alpha^2; s_{12} = 0, s_{13} = -B_0\alpha^2 \\
& s_{22} = D\alpha^2 + K_u, s_{23} = 3D\alpha^3, \\
& s_{33} = H_0\alpha^4 + A_0\alpha^5 + K_u
\end{align}
\]

\[
(A,B_0) = \int_{-h/2}^{h/2} Q_{11}(1,f(z_m)) dz; \\
(D,D_2) = \int_{-h/2}^{h/2} Q_{11}(z_m + c) (z_m + c), f(z_m)) dz; \\
H = \int_{-h/2}^{h/2} Q_{11} f(z_m) dz
\]

4. DISCUSSION OF RESULTS

In this study, bending analysis of simply supported FG beams subjected to a uniform load resting in elastic foundation of the type Winkler’ by using the hyperbolic shear deformation beam theory is suggested for investigation. Comparisons are made with available solutions in literature. In order to verify the accuracy of the present analysis, some numerical examples are solved. The first comparison of the power law modeling is given through comparison with elasticity solutions available in literature (Huu-Tai Thaï et al 2012) [1], (Lie et al 2010 [22]) give numerical results for the transverse deflections and stresses in an isotropic plate with power law variation in modulus subject to sinusoidal loading of the form. The material properties of the FGM are indicated in Table 1.

For numerical results, an Al/Al2O3 beam composed of aluminum (as metal) and alumina (as ceramic) is considered. The material properties of aluminum are \(E_s = 70\text{ GPa}, \rho_s = 2702 \text{ Kg/m}^3, \nu = 0.3\) and those of alumina are \(E_s = 380\text{ GPa}, \rho_s = 3960 \text{ Kg/m}^3\) (sismek2009) [9].

For convenience, the following dimensionless forms are used.
To illustrate the effect of power law index $p$ on the bending response of FG beams under uniform load, the axial displacement $u$, transverse deflection $w$, and axial stress $\sigma_z$, respectively are plotted in Figs. 3–4 and 5. Since there are no differences between the results of shear deformation beam theories, TBT is used only in Figs. 3–4 and 5. It can be seen that increasing the power law index $p$ will reduce the stiffness of the FG beams, and consequently, leads to an increase in the deflections and axial stress. This is due to the fact that higher values of power law index $p$ correspond to high portion of metal in comparison with the ceramic part, thus makes such FG beams more flexible.

The effect of elastic foundation factor $K_w$ on the nondimensional displacements $\bar{u}$ and $\bar{w}$ of FG beams is shown in Fig. 6. It is observed that an increase in the value of the elastic foundation factor $K_w$ leads to a reduction of the displacements for $p=10$, $a/h=5$.

Fig. 7 contains the nondimensional deflections for different value of the power law index $p$ results in a decrease in the value of elasticity modulus and the effect of elastic foundation. In other words, the beam becomes flexible as the power law index increases, thus decreasing the displacements values.

7. CONCLUSIONS

In this research the new high order shear deformation theory based on the concept of the neutral axis FG has been studied, and several numerical examples were presented and discussed to check the accuracy of the latter. The results obtained by the proposed theory are almost identical and are similar good results of the literature. There was an increase in the arrow and a reduction of the transverse deflection, this is due to the material increase, to the inclusion of the effects of shear deformation and to the factor of the elastic foundation.
